Plants need essential nutrients from the soil in order to grow and flourish. Just like us, if they don't get enough nutrients it can seriously affect their health. To coincide with the International Year of Plant Health in 2020, here's a look at how all 14 essential plant nutrients benefit plant health (in addition to improving yields):

**14 ESSENTIAL NUTRIENTS FOR IMPROVING AND PROTECTING PLANT HEALTH**

**NITROGEN**
Nitrogen is an essential component of amino acids for building proteins, nucleic acids, and chlorophyll which converts the sun’s energy into sugars. It is vital for plant metabolism, growth and health.

**PHOSPHORUS**
Phosphorus is vital for energy storage and transfer and membrane integrity in plants. Particularly important in early growth stages, it promotes tillering, root development, early flowering and ripening.

**POTASSIUM**
Potassium has major functions in enzyme activation, transpiration and the transport of assimilates (the products of photosynthesis). It helps plants to retain water during droughts, provides strength to plant cell walls and decreases susceptibility to diseases and insects.

**CALCIUM**
Calcium is needed for biomembrane maintenance. It helps in cell wall stabilization as an enzyme activator, in ammoration, and in the cation-anion balance and thus also plays important roles in resistance to diseases and abiotic stresses such as drought, heat and cold.

**MANGANESE**
Manganese plays a key role in a variety of plant functions including photosynthesis, enzyme activation, respiration, and nitrogen assimilation. Deficiencies can cause weaker structural resistance against pathogens and less tolerance to drought and heat stress.

**SULPHUR**
Sulphur is integral to all living plant cells and helps to produce amino acids involved in chlorophyll production, proteins and vitamins. It contributes to plant growth and seed formation, improves winter hardiness and helps plants resist diseases.

**CALCIUM**
Calcium is needed for biomembrane maintenance. It helps in cell wall stabilization as an enzyme activator, in ammoration, and in the cation-anion balance and thus also plays important roles in resistance to diseases and abiotic stresses such as drought, heat and cold.

**BORON**
Boron is required for cell wall synthesis and cell expansion. Boron deficiency disrupts reproductive growth, shoot and root growth and pollen viability and hence influences seed set and yield. A lack of boron can result in deformed leaves and poor quality of harvested product.

**MAGNESIUM**
Magnesium is central to the production of chlorophyll which is needed for photosynthesis and healthy green leaf tissue. It reduces crop stress caused by exposure to the sun and high temperatures, while a deficit can often cause stunted growth.

**MOLYBDENUM**
Molybdenum is used by plants to reduce nitrates into usable forms and for biological nitrogen fixation by certain species. Insufficient molybdenum can mean some plants can’t fix nitrogen from the air to make proteins and can hinder normal plant growth.

**NICKEL**
Nickel is important in plant seed germination, photosynthesis, enzyme functions and nitrogen metabolism. A deficiency affects plant growth, antioxidant systems and response to stress.

**ZINC**
Zinc participates in chlorophyll formation, is needed to activate many enzymes in plants and is needed for plant immune responses. As a result, it is important for increasing plant resistance to diseases and pests.

**IRON**
Iron is another essential component for creating chlorophyll and also serves as a catalyst for cell division which is central to plant growth. Many plants also use iron for their enzyme functions. A lack of iron results in yellowing leaves and poor fruit quality and quantity.

**CHLORINE**
Chlorine improves plant productivity, plays a role in photosynthesis and is needed for for animals and ionic balance. It can help to minimize water loss during stressful dry periods and enhance disease resistance.

**Copper**
Copper plays a key role in nitrogen and hormone metabolism and is needed for many enzyme activities in plants, as well as for chlorophyll and seed production. Deficiencies can lead to crop failure and increased susceptibility to diseases such as ergot.

**MANGANESE**
Manganese plays a key role in a variety of plant functions including photosynthesis, enzyme activation, respiration, and nitrogen assimilation. Deficiencies can cause weaker structural resistance against pathogens and less tolerance to drought and heat stress.

**SULPHUR**
Sulphur is integral to all living plant cells and helps to produce amino acids involved in chlorophyll production, proteins and vitamins. It contributes to plant growth and seed formation, improves winter hardiness and helps plants resist diseases.

**CALCIUM**
Calcium is needed for biomembrane maintenance. It helps in cell wall stabilization as an enzyme activator, in ammoration, and in the cation-anion balance and thus also plays important roles in resistance to diseases and abiotic stresses such as drought, heat and cold.

**MAGNESIUM**
Magnesium is central to the production of chlorophyll which is needed for photosynthesis and healthy green leaf tissue. It reduces crop stress caused by exposure to the sun and high temperatures, while a deficit can often cause stunted growth.

**MOLYBDENUM**
Molybdenum is used by plants to reduce nitrates into usable forms and for biological nitrogen fixation by certain species. Insufficient molybdenum can mean some plants can’t fix nitrogen from the air to make proteins and can hinder normal plant growth.

**NICKEL**
Nickel is important in plant seed germination, photosynthesis, enzyme functions and nitrogen metabolism. A deficiency affects plant growth, antioxidant systems and response to stress.

**ZINC**
Zinc participates in chlorophyll formation, is needed to activate many enzymes in plants and is needed for plant immune responses. As a result, it is important for increasing plant resistance to diseases and pests.
